

Mail

Everything associated with mail has High rating as we are dealing with personal and confidential data. So no one else then the owner of the mail should have access. Therefore, mail is secured through the user authentication and authorization measures of the OS user account system. For the secure protocol `imaps` is used.

There are two elements to the UNIX mail system: Inbox and personal folders. The Inbox is physically located at the mail server to which no user has login rights. Inbox content can only be accessed after successful authentication. The personal mail folder structure resides inside the user home directory space. Both are accessed using the `dovecot` utility (based on `imaps` encrypted and authenticated protocol).

Sending mail is performed using the `submission` protocol which is both secure encrypted and authenticated.

See [here](#) how to setup you mail client.
